2004

"As seen from the experimental setup, the laser beam incident from the source on a plane mirror glued to the diaphragm of a speaker reflected to the detection unit. The plane mirror will vibrate at the same speaker's frequency. Laser light is allowed to fall on a photo electric device that converts the modulated beam into an electric current. This current signal is then amplified and the sound wave

can be heard at the speaker's frequency. When light hits the photoelectric device, photon energy is absorbed in the depletion layer generating hole and electron carriers, and is then connected as current at the electrodes before recombination. This current is fed into an electric circuit for further processing of filtration and amplification before information can be retrieved in the required form".
